Nightcap

the price tracker that **actually buys**

An AI agent that completes the purchase the moment your price hits — on a single-use **Rain** scoped card, receipted onchain on **Monad**.

1-min video ↗

THE PROBLEM

Trackers like Keepa tell you the price dropped.
They can't **act** on it.

The best deals land at 3 a.m. and last minutes. You get the alert when you wake up — and the deal is already gone. The notification was never the hard part. **Buying** was.

WHY NO TRACKER JUST BUYS FOR YOU

Nobody hands a bot their credit card.

To buy unattended, software needs real spending power. But one bug, one hallucination, one prompt injection — and it drains the account. So every tracker stops at the notification and leaves the risky part to you.

The missing piece was never the agent. It was a way to give it **bounded** authority.

THE SOLUTION

Pre-authorized, **not supervised.**

You set the boundary once. When the price hits, the agent mints a **Rain scoped card** for exactly that purchase and checks out — no human present.

Capped

Issued at exactly your max price. It cannot overpay.

MCC-locked

Locked to the merchant category. It cannot buy the wrong thing.

Single-use

One purchase, then the card auto-retires. No standing liability.

The MCC lock and single-use retirement are enforced by Rain at authorization — verified live, not our code. The cap is set on the card at issuance, and our policy layer refuses over-cap requests too. That's what makes hands-off buying safe enough to run while you sleep.

HOW IT WORKS

Four steps, one of them onchain.

1 Watch

The tracker polls the merchant every ~2s for the current price.

2 Trigger

Price $\leq$ your limit and you've authorized $\rightarrow$ the agent acts.

3 Mint & buy

POST /issuing/users/{id}/cards/scoped $\rightarrow$ a real Rain card capped + MCC-locked, then authorize the charge.

4 Receipt

A record of the purchase is written to our SpendLedger contract on Monad — tamper-proof.

IT'S REAL, NOT A MOCK

Every purchase leaves two receipts.

Live sandbox calls against Rain, and real writes to Monad mainnet. From an actual run in the deployed app:

The storefront in the demo stands in for the merchant — in production the agent monitors real listings. Price discovery is the easy half; issuing bounded spending authority and completing an unattended purchase is the half that didn't exist, and that's what's real here.

RAIN

```
card ••••0118
paid $35.00 / cap $40.00
MCC lock 5942 · single-use
txn 8dbddb48-08ad-4f8f-be18...
```

MONAD

```
SpendLedger contract
0xd435ecb4258b86cf36b0...
receipts confirmed on mainnet
```

[Verify on MonadScan](#) ↗

HOW IT MAPS TO THE CHALLENGES

All three, for real.

Best use of Rain

Scoped cards are the hero primitive — minted per purchase via the sandbox API, with amount cap, allowedMccs and single-use retirement enforced by Rain at authorization.

General track

A software agent initiates and completes a card transaction autonomously, the instant its pre-authorized condition is met. No human at checkout.

Best implementation of Monad

Every agent purchase settles a receipt onchain to a Solidity SpendLedger on Monad — an immutable answer to who spent what, on whose authority.

Set your price. Go to sleep. Wake up owning it.

Rain for the payment · **Monad** for the proof
